

Project Summary: Infrastructure as Code

In this project I will be using Terraform to setup an infrastructure on AWS within one virtual private cloud (VPC) that will contain 2 availability zones, 2 public networks, 2 private networks, web servers in the public networks that are load balanced and autoscaled, application servers in the private networks that are load balanced and autoscaled, database servers in the private networks, a NAT gateway for the VPC, and a CloudFront distribution with an S3 bucket. The created infrastructure is intended for a social media application project for 50,000 users. In addition to creating the infrastructure, monthly pricing estimates for the infrastructure have been provided to show the cost of 3 different scenarios. The 3 scenarios are for the initial build, increased performance and redundancy, and loss of on-demand instances.
